CSE315 Machine Learning – Week 2

Lab 1: Python Introduction

Dr. Feng Zhao

feng.zhao@xjtlu.edu.cn

D529, Science Building

Overview

- In this first lab, we will familiarize ourselves with Python and some of the main libraries.
- If you do not manage to complete the lab in the pre-designated hours, then please complete it in your own time as it will help you better understand some of the course materials.
- All the machines in the lab have the main Python libraries and environment you will need for the labs. If you are using your own machine, you can install the Anaconda distribution: <https://www.anaconda.com/downloads>, which includes most of the libraries.

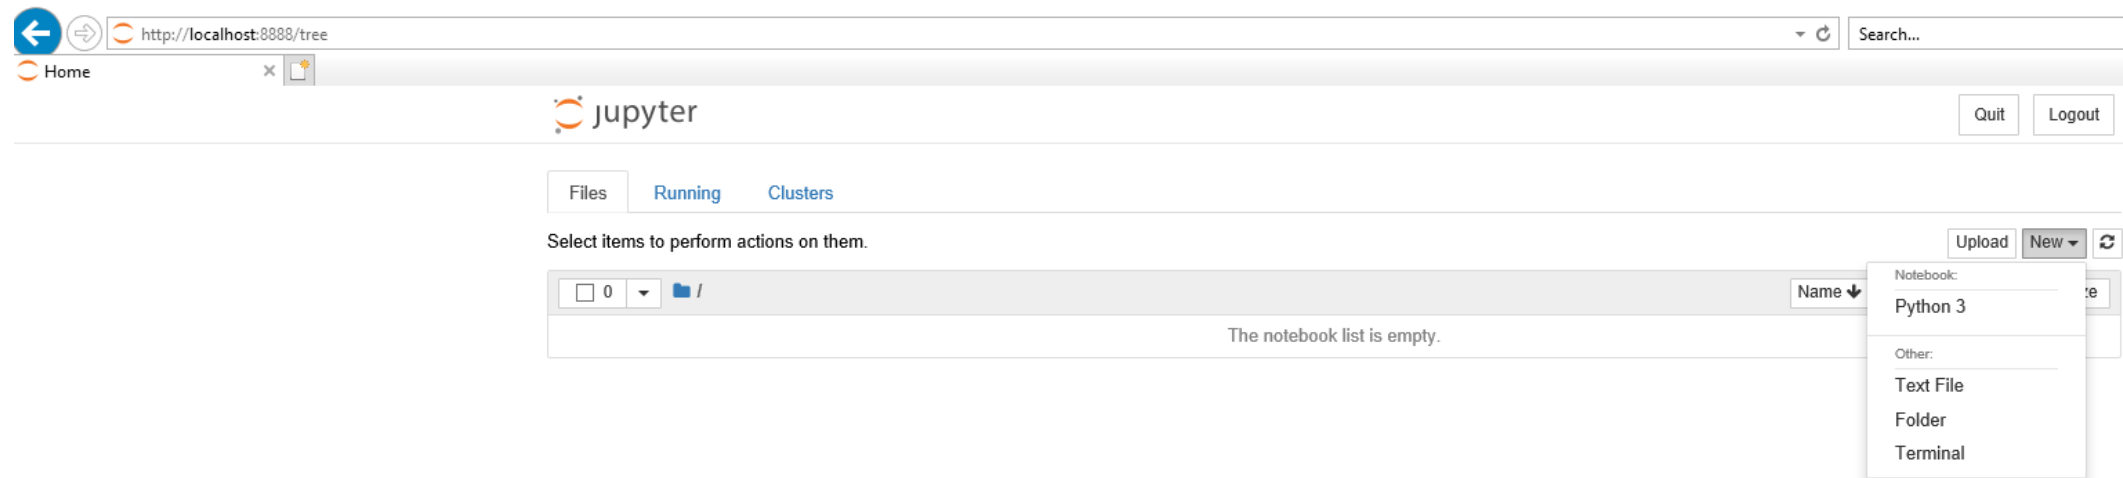

Editor/IDE

- Step 1: Search and run "Anaconda Prompt"
- Step 2: mkdir CSE315Lab
- Step 3: cd CSE315Lab
- Step 4: You will need an editor/IDE to develop your codes and if you don't have a preference, we recommend using the iPython Notebook.
- The Jupyter iPython Notebook can be launched by typing any of following 3 commands in a Terminal (Linux or Mac) or Command Prompt (Windows).

jupyter notebook or jupyter-notebook or ipython notebook

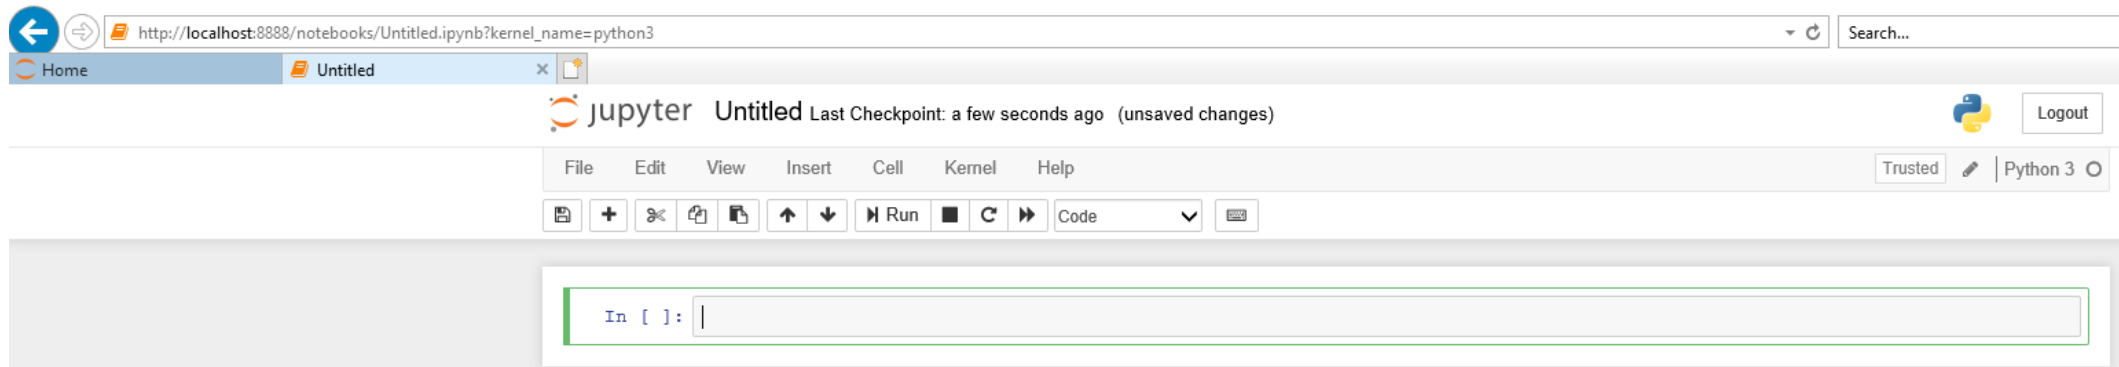

Editor/IDE, Cont.

- Step 5: To start a new notebook select the "New" button in the top right corner and select "Python3"

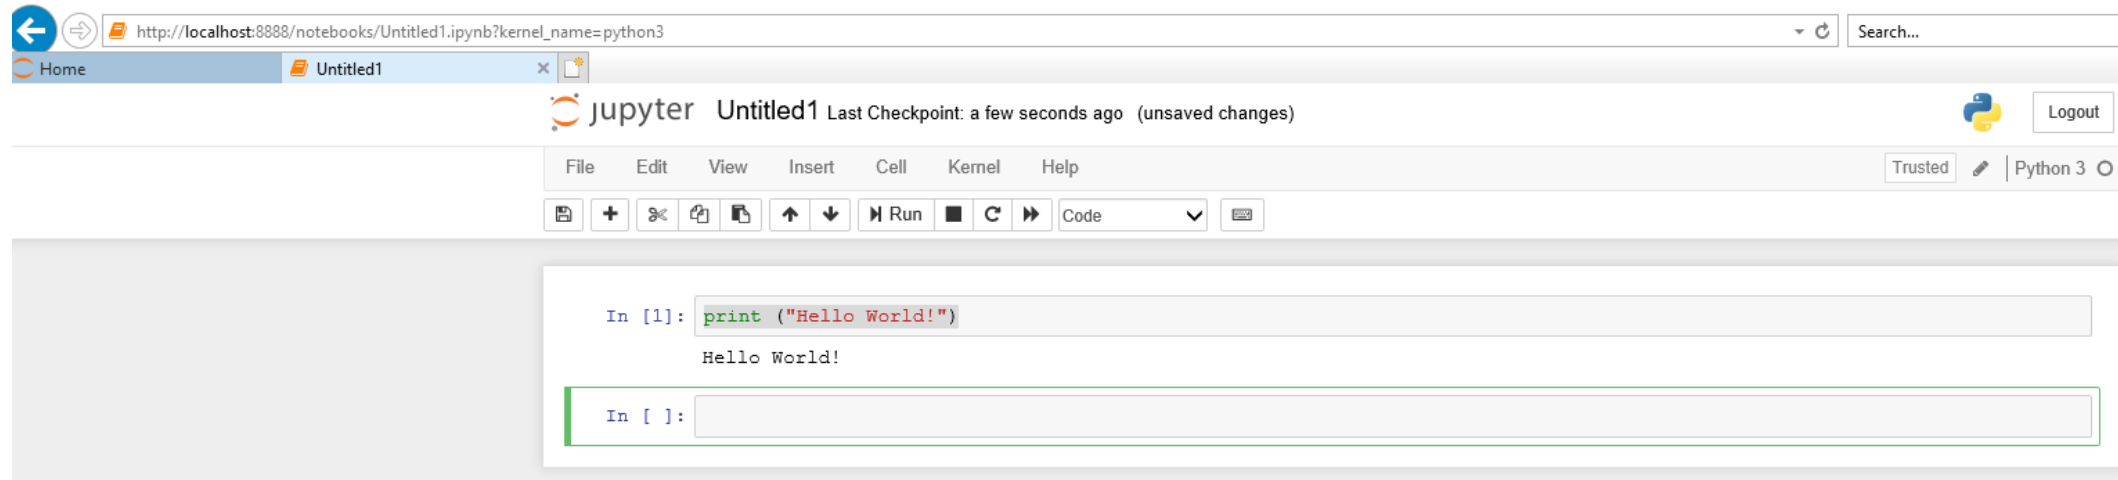

Editor/IDE, Cont.

- Step 6: The following image shows a basic interface of jupyter notebook. The interface splits into cells. Python code can be programmed in each cell. You can choose to run your python code in a single cell by (Shift+Enter or Ctrl+Enter) or the whole notebook by clicking on the menu Cell\Run All.

Editor/IDE, Cont.

The screenshot shows the Jupyter Notebook web interface in a browser. The address bar displays `http://localhost:8888/notebooks/Untitled1.ipynb?kernel_name=python3`. The notebook title is "Untitled1" and it indicates "Last Checkpoint: a few seconds ago (unsaved changes)". The menu bar includes File, Edit, View, Insert, Cell, Kernel, and Help. The toolbar contains icons for saving, adding cells, undo, redo, and running code. The code area shows a single cell with the following content:

```
In [1]: print ("Hello World!")  
Hello World!
```

Below the first cell is an empty input prompt: `In []:`

The screenshot shows a Jupyter Notebook cell with the following code:

```
In [38]: import pandas as pd  
import numpy as np  
  
male100 = pd.read_csv('male100.csv', header=0)  
mean = male100.mean()  
print mean['Time']
```

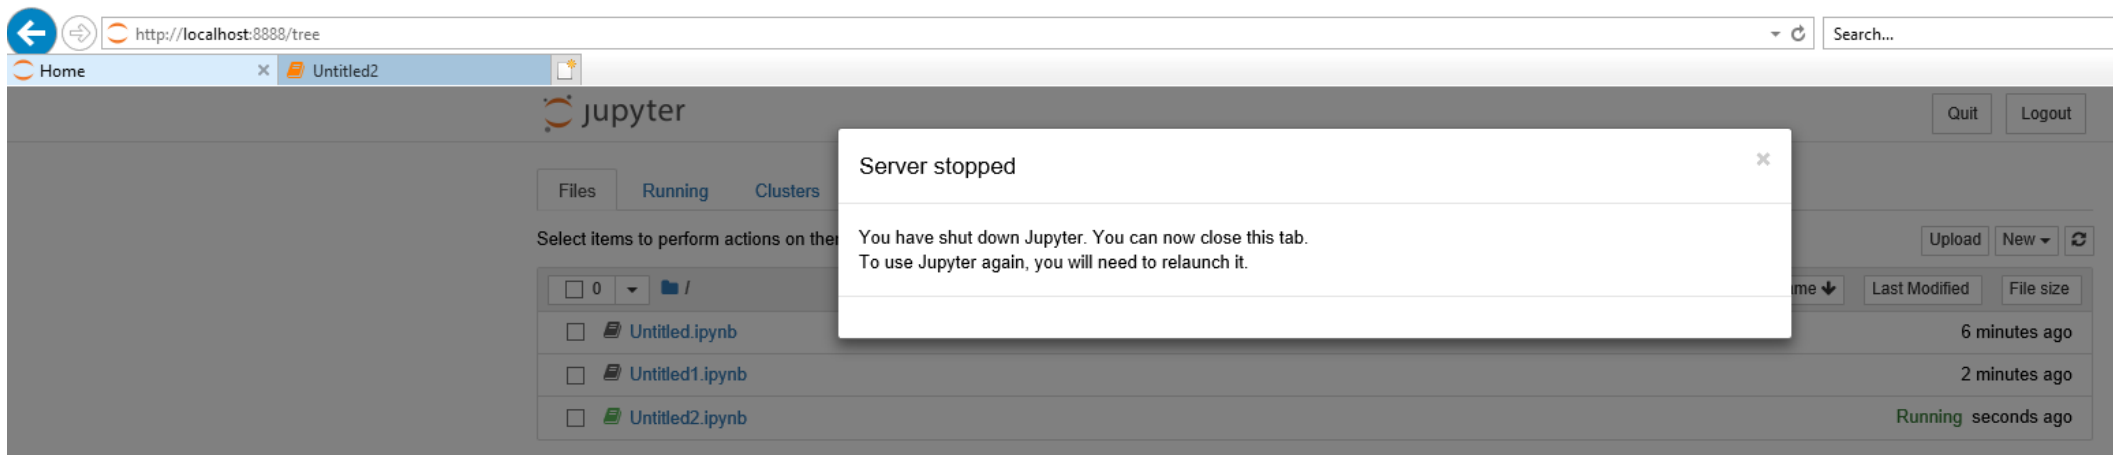

The output of the code is displayed below the cell:

```
10.3896296296
```

Below the output is an empty input prompt: `In []:`

Editor/IDE, Cont.

- Step 7: Choose Tab "Home" and click "Quit"

Python Quick Guide

- A good reference for Python:
<http://www.greenteapress.com/thinkpython/html/index.html>
- Here are a couple of general Python coding exercises to get you to start.

Example 1

- Listing 1 below demonstrates basic Python syntax.
- Unlike many other languages that use a semicolon(;) to indicate the end of the statement, Python has no mandatory statement termination characters, however it is whitespace sensitive (i.e., you must indent your code properly).
- In addition, Python is dynamically, implicitly typed (i.e., you don't have to declare variables). Comments in Python start with the hash character #, and extend to the end of the physical line.

Listing 1: Basic Python Syntax

```
#Declaring variable type is not required
a_string = "hello, world"
an_integer = 12
a_float = 3.14
5 a_boolean = True

#To print a constant or variable, use commas to print several items,
print a_string, an_integer, a_float, a_boolean, "\n"

10 #A long statement may be split into different lines with a backslash:
print 'a long statement may be split using backslash', \
    'this is still the same statement', "\n"

#Indentation Example
15 x = 10
    if x == 10:
        print ('x has a value of 10')
    else:
        print ('x does NOT have a value of 10')
```

Example 2

- Listing 2 introduces the use of lists and dictionaries as data structures in Python. These are the building blocks for other various Python data structures, including DataFrames that can be used to store instances of data (similar to records in a database).

```
myList = [1,2,3,4]

#range() creates a list of numbers between 0 and 10 in increments of 1
myList2 = range(0,10,1) #list of numbers 0 to 10

5 #this appends the object myList to the end of myList2 - i.e. the last element of
  #myList2 is a list
  myList2.append(myList)
  print myList2

10 #remove(x) removes the first element in the list that matches x
    myList2.remove(myList)

    #to add each element of myList to myList2, we can use a for loop
15 for x in myList:
    myList2.append(x)
    print myList2

    #len(x) returns the length of x
20 print len(myList2)

    #the sort function can take additional parameters such as a key,
    #ascending/decending etc
    myList2.sort()

25 #slicing lists - allows you to select segments of the list
    print myList2[2:4]
    print myList2[:3] # first 3 elements

30 #dict contain key value pairs
    myDict = {'a':'hello','b':'world'}
    print myDict['a']
    print myDict['b']
```

Example 3

- Listing 3 shows how functions can be defined within Python scripts.

Listing 3: Example Python function

```
#This Fuction output the result 1+1
def onePlusOne():
    return 1+1

5 #This function prints a passed string
def printme( str ):
    print str
    return

10 #Function Return sum of input values a and b
def add (a,b):
    return a+b

#Call Function
15 x = onePlusOne()
    y = add(1,2)

#native print fuction == printme()function
    print x
20 printme(y)
```

Example 4: Pandas Quick Guide

- Pandas is a Python library that provides easy-to-use data structures and data analysis tools. As Pandas is built on top of the Numpy package, both Pandas and Numpy packages are usually required to be imported for complete functionality.
- Listing 4 below demonstrates how to import and export dataset in pandas. All the data imported will be stored into a data structure called a DataFrame. For more details on Pandas functions, see the API Reference at <http://pandas.pydata.org/pandas-docs/stable/api.html>.

Listing 4: Introduction of Pandas

```
#imports the Pandas and Numpy libraries and gives aliases pd/np.
import pandas as pd
import numpy as np

5 #import csv file. If file contains header row, set header to the line 0
  #the import dataset will be stored into DataFrame (male100)
  male100 = pd.read_csv('male100.csv',header=0)
  print male100

10 #output male100 dataset to demo.csv file
   male100.to_csv('demo.csv')
```

Example 4: Pandas Quick Guide, Cont.

- The table below is the output of printing the Male100 DataFrame. This dataset contains Olympics men's 100 metres winning times for each Olympic year. In the later exercises, you will need to evaluate this dataset, which is available on the module webpage.

	Year	Time
0	1896	12.00
1	1900	11.00
2	1904	11.00
3	1906	11.20
4	1908	10.80
5	1912	10.80
6	1920	10.80
...

Example 5

- Pre-processing a dataset is often crucial in order to obtain a more accurate ML model. The following example provides some basic data processing functions available in Pandas.
- In general, it is a good practice to perform pre-processing stages on a copy of the original DataFrame, so that the original data remains unaltered. To do this use `copydf = df.copy()`, as `copydf = df` only passes by reference, therefore changes made to `copydf` will affect the original DataFrame.

Listing 5: Data Processing

```
import pandas as pd
import numpy as np

male100 = pd.read_csv('male100.csv', header=0)

5  #Each Column can be extracted by "dataframe name[column name]"
    print male100['Time'], "\n"

    #Calculate mean and standard deviation
10  #other common functions also available: max(), median()...
    mean = male100['Time'].mean()
    std = male100['Time'].std()

    #To get some basic statistics, we can use the describe() method:
15  print male100['Time'].describe(), "\n"

    print mean, std
```

Example 6

- Listing 6 introduces basic graph plotting.

Listing 6: Basic Plotting

```
#This magic command is used to activated the inline graph display
%matplotlib inline

import pandas as pd
5 import numpy as np

#import 'matplotlib.pyplot' to plot a simple stright line
import matplotlib.pyplot as plt

10 male100 = pd.read_csv('male100.csv',header=0)
    female100 = pd.read_csv('female100.csv',header=0)

#Basic pandas plotting
male100.plot(x=0,y=1, kind='scatter', color='g', marker='v', label="Mens 100m")
15

#Simplified Version
male100.plot.scatter(0,1, color='g', label="Mens 100m")

#Two different dataset in one graph
20 ax = male100.plot(x=0,y=1, kind='scatter', color='g', label="Mens 100m")
    female100.plot(x=0,y=1, kind='scatter', color='r', label="Womens 100m", ax = ax)

#we can use plt(imported from matplotlib) to plot a simple graph
#define a graph with repect to the all Olympic Years in male100.csv
25 y = -0.014*male100['Year']+38
    plt.plot(male100['Year'],y,'r-',color = 'r')
```

Example 6, Cont.

- The above code uses the function `DataFrame.plot(x, y, kind, color, label, ax)`. The first two parameters indicate which columns of the DataFrame will be used for the x and y axes. `color` is used to assign a colour to data points, `marker` defines their shape, and `label` gives the graph a name. `kind` allows the plotting method to be set, the default is line, however, many other plotting methods are available.
- `DataFrame.plot()` API
<http://pandas.pydata.org/pandasdocs/stable/generated/pandas.DataFrame.plot.html>
- Additional colour options:
http://matplotlib.org/api/colors_api.html
- Marker shapes:
http://matplotlib.org/api/markers_api.html
